#### Abstract

Organic azide complexes $\left[O s\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{R}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4} \quad(\mathbf{1}, \mathbf{2}) \quad\left[\mathrm{R}=\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{5}\right.$ (a), $\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CH}_{3}$ (b), $\mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{C}_{6} \mathrm{H}_{5}$ (c), $\mathrm{C}_{6} \mathrm{H}_{5}$ (d); $\mathrm{R1}=\mathrm{Me}$ (1), Et (2)] were prepared by allowing bromo-compounds $\left[\mathrm{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$ to react first with AgOTf and then with an excess of azide in toluene. Benzylazide complexes reacted in solution leading to imine derivatives $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left\{\kappa^{1}-\mathrm{NH}=\mathrm{C}(\mathrm{R} 2) \mathrm{Ar}\right\}\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}(\mathbf{3}, 4)\left[\mathrm{R} 2=\mathrm{H}(\mathbf{a}, \mathbf{b}), \mathrm{CH}_{3}(\mathbf{c}) ; \mathrm{Ar}=\mathrm{C}_{6} \mathrm{H}_{5}, \mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CH}_{3}\right.$; $\mathrm{R} 1=\mathrm{Me}(\mathbf{3}), \mathrm{Et}(4)]$. Phenylazide, on the other hand, reacted in solution affording the dinuclear dinitrogen complex $\left[\left\{\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left[\mathrm{P}(\mathrm{OMe})_{3}\right]\right\}_{2}\left(\mu-\mathrm{N}_{2}\right)\right]\left(\mathrm{BPh}_{4}\right)_{2}$ (5). Depending on the nature of the R substituent, the reaction of the $p$-cymene complex $\left[\mathrm{OsCl}_{2}\left(\eta^{6}-p\right.\right.$-cymene) $\left.\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$ with $\mathrm{RN}_{3}$ yielded imine $\left[\mathrm{OsCl}\left(\eta^{6}-p-c y m e n e\right)\left\{\kappa^{1}-\mathrm{NH}=\mathrm{C}(\mathrm{H}) \mathrm{Ar}\right\}\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4} \quad(6) \quad\left(\mathrm{Ar}=\mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CH}_{3}\right)$ and amine derivatives $\left[\mathrm{OsCl}\left(\eta^{6}-p\right.\right.$-cymene $\left.)\left(\kappa^{1}-\mathrm{NH}_{2} \mathrm{C}_{6} \mathrm{H}_{5}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4}$ (7). The complexes were characterised spectroscopically (IR, $\left.{ }^{1} \mathrm{H},{ }^{31} \mathrm{P},{ }^{15} \mathrm{~N} N M R\right)$ and by the X -ray crystal structure determination of $\left[\left\{\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left[\mathrm{P}(\mathrm{OMe})_{3}\right]\right\}_{2}\left(\mu-\mathrm{N}_{2}\right)\right]\left(\mathrm{BPh}_{4}\right)_{2}(5)$.

## Introduction

Organic azides are reported to react with transition metal complexes to give metal imido derivatives. ${ }^{1-4}$ Generally, the interaction of $\mathrm{RN}_{3}$ with a metal complex leads to a transient $\mathrm{M}-\mathrm{N}_{3} \mathrm{R}$ species, which subsequently may extrude $\mathrm{N}_{2}$ to give a terminal $\mathrm{M}=\mathrm{NR}$ derivative. ${ }^{2,4}$ However, in some cases, the metal $\kappa^{1}-\mathrm{N}_{3} \mathrm{R}$ intermediate results stable and can be isolated as a metal complex and characterised. ${ }^{5-9}$ Although there is significant interest in these intermediates, their isolation and characterisation is difficult and stable metal complexes containing organic azide ligands are rare. ${ }^{5-9}$ Examples include V(v), $\mathrm{Fe}(\mathrm{I})$, $\mathrm{Ta}(\mathrm{v})$ and $\mathrm{W}(\mathrm{v})$ mononuclear derivatives ${ }^{5}$ containing the bent moiety NNN [A] (Chart 1); $\mathrm{Cu}(\mathrm{I}), \mathrm{Ag}(\mathrm{I}), \mathrm{Pd}(\mathrm{II})$ and $\operatorname{Ir}(\mathrm{III})$ derivatives $^{6,7 a}$ with "linear" organoazide ligands [B] and [C]; and a $\mathrm{Ni}(0)$ complex ${ }^{8}$ with $\eta^{2}$-coordination of the $\mathrm{RN}_{3}$ ligand [E]. A mixed-metallic $\operatorname{Zr}(\mathrm{Iv})-\operatorname{Ir}(\mathrm{III})$ complex, containing a bridging PhNNN group [D], is also reported. ${ }^{9}$

[^0]We have a long-standing interest in the chemistry of diazo and triazo complexes of transition metals and have previously reported on the synthesis and reactivity of the hydrazine, diazene, diazenide, triazene and diazoalkane derivatives of $\mathrm{Mn}^{10}$ and $\mathrm{Fe}^{11}$ triads. More recently, we have also given an account of the first benzylazide complexes of iridium(III) ${ }^{7}$ and osmium $(\mathrm{II})^{12}$ stabilised by phosphites $\mathrm{P}(\mathrm{OR})_{3}$ or mixed-ligand $\mathrm{PPh}_{3}-\mathrm{P}(\mathrm{OR})_{3}$ as the supporting ligands. These studies have now been extended to half-sandwich fragments to test whether stable organic azide complexes can be prepared. The results of these studies, which allowed the preparation of new azide complexes of osmium, are reported here.

## Results and discussion

## Cyclopentadienyl complexes

Half-sandwich organic azide complexes of osmium $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{R}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}(\mathbf{1}, 2)$ were prepared by reacting bromo-compounds [ $\left.\mathrm{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$ first with AgOTf and then with an excess of the appropriate azide in toluene, as shown in Scheme 1.

The reaction of bromo-compounds $\left[\operatorname{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\right.$ $\left.\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$ with AgOTf proceeds with the separation of solid AgBr and the formation of triflato complexes [ $\mathrm{Os}\left(\mathrm{\kappa}^{1}-\mathrm{OTf}\right)$ $\left.\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$, which were not separated. The treatment of this species with an excess of organic azide $\mathrm{RN}_{3}$ afforded azide derivatives $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{R}\right)\left(\mathrm{PPh}_{3}\right)\right.$ $\left.\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{OTf}$, which separated out from their toluene solutions as dark-green gummy products. The related tetraphenylborate salts $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{R}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}(\mathbf{1}, 2)$ were obtained as solids by treating the triflate species with an excess of $\mathrm{NaBPh}_{4}$ in ethanol. Also, the related bis(triphenylphosphine) complex $\left[\operatorname{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)_{2}\right]$ does not give any azide complex after treatment first with AgOTf and then with an excess of organic azide and is worth noting. Therefore, it seems that only mixed-ligand fragments $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\right.$ $\left.\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$ can stabilise the $[\mathrm{Os}]-\mathrm{K}^{1}-\mathrm{N}_{3} \mathrm{R}$ derivatives.

Azide complexes $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{R}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}$ $(1,2)$ are green solids stable in air but rather unstable in a solution of polar organic solvents, where they behave as $1: 1$ electrolytes. ${ }^{13}$ Analytical and spectroscopic data (IR, ${ }^{1} \mathrm{H},{ }^{15} \mathrm{~N}$, ${ }^{31} \mathrm{P}$ NMR) support the proposed formulation.

The IR spectra of complexes 1 and 2 show a medium-intensity band at $2164-2145 \mathrm{~cm}^{-1}$, attributed to $\nu_{\mathrm{N}_{3}}$ of the coordinate azide ligand. Support for this attribution comes from the spectra of the labelled compounds $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-{ }^{15} \mathrm{~N}_{3} \mathrm{R}\right)\right.$ $\left.\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}\left(\mathbf{1} \mathbf{b}_{\mathbf{1}}, \mathbf{2 b}_{\mathbf{1}}\right.$, and $\left.\mathbf{1} \mathbf{c}_{\mathbf{1}}\right)$, which show the $\nu_{{ }^{15} \mathrm{~N}_{3}}$ at 2117-2105 $\mathrm{cm}^{-1}$ shifted to a lower wavenumber by $30-50 \mathrm{~cm}^{-1}$ with respect to unlabelled compounds $\mathbf{1 b}, \mathbf{2 b}$ and 1c (Fig. 1; ESI, Fig. S1 and S2 $\dagger$ ).

In addition, the high $\nu_{\mathrm{N}_{3}}$ values of our complexes, compared to those of azide complexes, the X-ray structures of which are known, ${ }^{6,7 a}$ suggest the $\kappa^{1}$-diazoamino coordination mode (Scheme 2) of the azide ligand.

Further support for the coordination of the azide is given by the ${ }^{15} \mathrm{~N}$ NMR spectra of the labelled complexes $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\right.$

Scheme $1 \mathrm{R}=\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{5}$ (a), $\mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CH}_{3}$ (b), $\mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{C}_{6} \mathrm{H}_{5}$ (c), $\mathrm{C}_{6} \mathrm{H}_{5}(\mathrm{~d}) ; \mathrm{R} 1=\mathrm{Me}(1), \mathrm{Et}(2)$.

Fig. 1 IR spectra in KBr of the labelled [Os $\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-{ }^{15} \mathrm{~N}_{3} \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4}{ }^{-}\right.$ $\left.\left.4-\mathrm{CH}_{3}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4} \quad\left(2 \mathrm{~b}_{1}\right)$ and unlabelled compound $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CH}_{3}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4}(2 \mathrm{~b})$.

Scheme 2
$\left.\left(\kappa^{1}{ }^{15} \mathrm{~N}_{3} \mathrm{R}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}\left(\mathbf{1} \mathbf{b}_{\mathbf{1}}\right.$ and $\left.\mathbf{1} \mathbf{c}_{\mathbf{1}}\right)$. These show a multiplet between 139 and 117 ppm and a singlet near 213 ppm , attributed to the $\mathrm{N} \gamma$ and $\mathrm{N} \alpha$ nitrogen nuclei, respectively, of the coordinate ${ }^{15} \mathrm{~N}_{3} \mathrm{R}$ group. The ${ }^{31} \mathrm{P}$ NMR of the labelled complexes $\mathbf{1 b}_{\mathbf{1}}, \mathbf{2 b}_{\mathbf{1}}$ and $\mathbf{1} \mathbf{c}_{\mathbf{1}}$ also support the coordination of the azide, showing a multiplet due to coupling with the ${ }^{15} \mathrm{~N}$ nuclei of $\kappa{ }^{1}-{ }^{15} \mathrm{~N}_{3} R$, which can be simulated using an AXN model ( $\mathrm{A}, \mathrm{X}={ }^{31} \mathrm{P} ; \mathrm{N}={ }^{15} \mathrm{~N}$ ) with the parameters reported in the Experimental section. The good fit between the experimental and calculated spectra further supports the presence of the coordinated azide.

In addition to the resonances of the substituents of the organic azides $\mathrm{RN}_{3}$, the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{1}, 2$ show the characteristic signals of the ancillary ligands $\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}, \mathrm{PPh}_{3}$, and $\mathrm{P}(\mathrm{OR} 1)_{3}$ and of the $\mathrm{BPh}_{4}{ }^{-}$anion, in agreement with the half-sandwich geometry shown in Scheme 1.

Transition metal complexes containing organic azides $\mathrm{RN}_{3}$ as ligands are rare ${ }^{5-9}$ and only one example is known for osmium, ${ }^{12}\left[\mathrm{OsCl}\left(\eta^{1}-\mathrm{N}_{3} \mathrm{CH}_{2} \mathrm{Ar}\right)(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{2}\left\{\mathrm{P}(\mathrm{OR})_{3}\right\}\right] \mathrm{BPh}_{4}$, involving carbonyl and phosphines as the supporting ligands. The use of the half-sandwich fragment $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]^{+}$
allows new stable organic azide complexes to be prepared. Unfortunately, the bonding mode of the $\mathrm{RN}_{3}$ in our compounds 1 and 2 could not be established by X-ray determination, owing to their instability in solution, which prevented the preparation of suitable crystals. However, IR data offer information suggesting linear $\mathrm{N} \gamma$ coordination (Scheme 2). Values for $\nu_{\mathrm{N}_{3}}\left(2164-2145 \mathrm{~cm}^{-1}\right)$ higher than those of free $\mathrm{RN}_{3}$ were found in our complexes 1 and 2 and in those of Ir, Pd, Cu , and Ag , in which $\mathrm{N} \gamma$ coordination was confirmed by X-ray crystal structure determination. Such coordination through substituted $\mathrm{N} \gamma$ is favoured by the greater Lewis basicity ${ }^{14}$ of the site and is probably the most common type of azide complex with linear NNN geometry.

Azide complexes [ $\left.\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{CH}_{2} \mathrm{Ar}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$ $\mathrm{BPh}_{4}$ and $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left\{\kappa^{1}-\mathrm{N}_{3} \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{C}_{6} \mathrm{H}_{5}\right\}\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$ $\mathrm{BPh}_{4}$ (1a-c, 2a-c) are stable as solids but react slowly in solution to give new compounds, characterised as the imine species $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left\{\mathrm{K}^{1}-\mathrm{NH}=\mathrm{C}(\mathrm{H}) \mathrm{Ar}\right\}\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}$ and $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left\{\mathrm{K}^{1}-\mathrm{NH}=\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{C}_{6} \mathrm{H}_{5}\right\}\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}(\mathbf{3}, 4)$ (Scheme 3).

The extrusion of $\mathrm{N}_{2}$ in the cooordinated azide complexes 1 and 2 followed by the 1,2 -shift of one hydrogen atom may lead to the formation of the imino derivatives 3 and 4 . Both the cis and trans isomers of the imine ligand are formed in the reaction of (1-azidoethyl)benzene derivatives $\mathbf{1 c}$ and $3 \mathbf{c}$ in approximately a $1: 4$ ratio, whereas, with the benzylazide, only trans isomers $\mathbf{3 a}, \mathbf{b}$ and $\mathbf{4 a}, \mathbf{b}$ are formed.

Surprisingly, the phenylazide complex $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{N}_{3} \mathrm{Ph}\right)\right.$ $\left.\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}\right] \mathrm{BPh}_{4} \quad(\mathbf{1 d})$ is also unstable in solution, affording a moderate yield of a blue solid characterised as a dinuclear $\mu$-dinitrogen complex of the type $\left[\left\{\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\right.\right.$ $\left.\left.\left[\mathrm{P}(\mathrm{OMe})_{3}\right]\right\}_{2}\left(\mu-\mathrm{N}_{2}\right)\right]\left(\mathrm{BPh}_{4}\right)_{2}(5)$ (Scheme 4).

The formation of the $\mu-\mathrm{N}_{2}$ complex is not, in part, unexpected because the decomposition of the coordinated azide with the extrusion of $\mathrm{N}_{2}$ cannot give an imine owing to the

Scheme $3 \mathrm{Ar}=\mathrm{C}_{6} \mathrm{H}_{5}(\mathrm{a}), 4-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4}(\mathrm{~b})$.

Scheme 4
absence of appropriate hydrogen atoms adjacent to the coordinate nitrogen. Therefore, the fragment $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\right.$ $\left.\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}\right]^{+}$does coordinate either $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~N}$ giving imido [Os] $=$ $\mathrm{NC}_{6} \mathrm{H}_{5}$, or $\mathrm{N}_{2}$ affording dinuclear $\mu-\mathrm{N}_{2}(5)$ as the final product. Alternatively, the formation of the dinitrogen complex may be explained on the basis of the mechanism depicted in Scheme $5,{ }^{5 e}$ previously proposed for the formation of the nitrene complexes of vanadium.

Loss of nitrene may occur directly from the azide complex 1d (or an isomer thereof) affording a dinitrogen intermediate (I), which then dimerises to give 5 . Also the nitrene fragments thus generated may dimerise to give diazene $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~N}=\mathrm{NC}_{6} \mathrm{H}_{5}$ as a final product.

The formation of 5 highlights the greater avidity of the fragment $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}\right]^{+}$for the dinitrogen molecule allowing the preparation of new $\mu-\mathrm{N}_{2}$ complexes. In addition, whatever may be the mechanism, the formation of 5 is interesting and has no precedents in azide derivative reactions.

Both imine complexes $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left\{\mathrm{K}^{1}-\mathrm{NH}=\mathrm{C}(\mathrm{H}) \operatorname{Ar}\right\}\left(\mathrm{PPh}_{3}\right)\right.$ $\left.\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}$ and $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left\{\kappa^{1}-\mathrm{NH}=\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{C}_{6} \mathrm{H}_{5}\right\}\left(\mathrm{PPh}_{3}\right)\right.$ $\left.\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4} \quad(3,4)$ and the dinitrogen derivative $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}_{2}\left(\mu-\mathrm{N}_{2}\right)\right]\left(\mathrm{BPh}_{4}\right)_{2}$ (5) were separated as green-yellow $(3,4)$ or blue $(5)$ solids, stable in air and in solution of polar organic solvents, where they behave as $1: 1$ $(3,4)$ or 2:1 (5) electrolytes. ${ }^{13}$ Analytical and spectroscopic data (IR, ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P},{ }^{15} \mathrm{~N}$ NMR) support the proposed formulation, which is further confirmed by X-ray crystal structure determination of the $\mu-\mathrm{N}_{2}$ complex $\left[\left\{\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\right.\right.$ $\left.\left.\left[\mathrm{P}(\mathrm{OMe})_{3}\right]\right\}_{2}\left(\mu-\mathrm{N}_{2}\right)\right]\left(\mathrm{BPh}_{4}\right)_{2}(5)$, the ORTEP $^{15}$ of which is shown in Fig. 2.

The asymmetric unit contains a tetraphenylborate anion, a dichloromethane solvent molecule and one half of the osmium cation complex so that the whole cation contains two symmetrically related osmium atoms in a half-sandwich piano-stool coordination. Each is bonded by one cyclopentadienyl (Cp), one $\mathrm{P}(\mathrm{OMe})_{3}$ phosphite, one $\mathrm{PPh}_{3}$ phosphine and one bridging N - $\mathrm{N}^{\prime}$-dinitrogen ligand, where the last ligand presents the inversion centre in the middle of the $\mathrm{N}-\mathrm{N}$ bond. The overall geometry of the half-sandwich piano-stool complex is a slightly distorted octahedral and is marked by the angles between the centroid of the Cp ligand (Ct1) and the legs close

Scheme 5 [Os] $=\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}\right]^{+}$.

Fig. 2 Molecular structure of 5.
to the theoretical $125.3^{\circ}$, or by near $90^{\circ}$ values for angles formed by the legs of the piano-stool (see Table 1). The two OsCpP 2 fragments are rotated about the Os-Os vector by $180^{\circ}$. Coordination of the Cp ligand (ring-slippage, $0.025 \AA$ ) with Os-C distances between $2.229(4)$ and $2.260(4) \AA$ (average, $2.244 \AA$ ) do not require further comments as they are similar, for example, to those found in the cation $\left[\mathrm{CpOs}\left(=\mathrm{C}=\mathrm{CH}_{2}\right)\right.$ $\left.\left(\mathrm{PPh}_{3}\right)_{2}\right]^{+}$, Os-C(Cp) 2.25-2.30(2), av. $2.27 \AA .{ }^{16}$ The Os-P distances are 2.261(1) and 2.342(1), longer than that of the phosphine ligand, but with less back-bonding than the phosphite ligand. The bond length $\mathrm{Os}-\mathrm{N}(1), 1.957(3) \AA$, is quite similar to those found for the $\operatorname{Os}($ II $)$ cation $\left[\left\{\left(\mu-\mathrm{N}_{2}\right) \operatorname{Cp}{ }^{*} \operatorname{Os}\left(\mathrm{Me}_{3} \mathrm{P}\right)_{2}\right\}_{2}\right]^{2+}$, 1.959 (8) and $1.979(7) \AA,{ }^{17}$ and slightly longer than those found in mixed-valence ( $\mathrm{II}+{ }_{\mathrm{III}}$ ) CpOs complexes, between 1.883(6) and $1.895(5) \AA .{ }^{18}$ The $\mathrm{N}-\mathrm{N}$ bond length, 1.116(6) $\AA$ is, however, shorter than those found in the above-mentioned compounds and, namely, between $1.135(6)$ and $1.165(8) \AA$. Conversely, the Os-N-N angle, $177.2(4)^{\circ}$, is more linear than the one found in the above-mentioned complexes (around $170^{\circ}$ ) or even in the ruthenium analogous complex $\left[\left\{\left(\mu-\mathrm{N}_{2}\right) \mathrm{CpRu}\left(\mathrm{PEt}_{3}\right)_{2}\right\}_{2}\right]^{2+} .{ }^{19}$

Symmetry transformations used to generate equivalent atoms: i: $1-x$; $1-y, 2-z$.

The IR spectra of the imine complexes 3 and 4 show a medium-intensity band at $3260-3282 \mathrm{~cm}^{-1}$, attributed to the $\nu_{\mathrm{NH}}$ of the imine ligand. Its presence is confirmed by ${ }^{1} \mathrm{H}$ NMR spectra which, in monosubstituted species [Os]-NH $=\mathrm{C}(\mathrm{H}) \mathrm{Ar}$ $(\mathbf{3 a}, \mathbf{3 b}, \mathbf{4 a}, \mathbf{4 b})$, show a slightly broad doublet between 10.16 and 10.79 ppm , attributed to the NH imine resonance. This attribution is supported by the spectra of the labelled complexes [Os]- ${ }^{15} \mathrm{NH}=\mathrm{C}(\mathrm{H}) \mathrm{Ar}\left(\mathbf{3} \mathbf{b}_{\mathbf{1}}, \mathbf{4 b}_{\mathbf{1}}\right)$ (ESI, Fig. S3 $\dagger$ ), which show a doublet of multiplets due to the coupling of the H imine with the $=\mathrm{C}(\mathrm{H})$ proton and the ${ }^{31} \mathrm{P}$ and the ${ }^{15} \mathrm{~N}$ nuclei.

These spectra may be simulated using an AXNYZ model (A, X $={ }^{31} \mathrm{P} ; \mathrm{N}={ }^{15} \mathrm{~N} ; \mathrm{Y}, \mathrm{Z}={ }^{1} \mathrm{H}$ ) with the parameters reported in the Experimental section and a good fit between the calculated and experimental spectra (ESI, Fig. S3 $\dagger$ ) strongly supports the proposed attribution. Noticeably, a doublet between 8.41 and 8.80 ppm also appears in the spectra, which is correlated with the doublet at $10.16-10.79 \mathrm{ppm}$ of the NH proton in a COSY experiment and was attributed to the $=\mathrm{C}(\mathrm{H})$ of the imine.

In the temperature range between +20 and $-80^{\circ} \mathrm{C}$, the ${ }^{31} \mathrm{P}$ NMR spectra of the imine derivatives $\mathbf{3 a}, \mathbf{3 b}, \mathbf{4 a}$ and $\mathbf{4 b}$ are AX quartets, whereas those of the labelled compounds $\mathbf{3} \mathbf{b}_{\mathbf{1}}$ and $\mathbf{4} \mathbf{b}_{\mathbf{1}}$ appear as AXN multiplets ( $\mathrm{N}={ }^{15} \mathrm{~N}$ ). In addition, the proton-coupled ${ }^{15} \mathrm{~N}$ NMR spectra are doublets of multiplets that have been simulated by use of an AXNYZ model with the parameters reported in the Experimental section. The good fit between the calculated and the experimental spectra supports the proposed half-sandwich piano-stool geometry of the type depicted in Scheme 1 for our imine complexes.

The ${ }^{1} \mathrm{H}$ NMR spectra of the complexes $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\right.$ $\left.\left\{\kappa^{1}-\mathrm{NH}=\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{C}_{6} \mathrm{H}_{5}\right\}\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}(3 \mathrm{c}, 4 \mathrm{c})$ show two broad signals between 10.46 and 9.98 ppm , which may be attributed to the NH imine protons of the two isomers cis and trans (Scheme 3) present in the sample. This attribution is supported by the ${ }^{1} \mathrm{H}$ NMR spectra of the labelled complexes $\left[\mathrm{Ru}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left\{\mathrm{\kappa}^{1-15} \mathrm{NH}=\mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{C}_{6} \mathrm{H}_{5}\right\}\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}\left(3 \mathbf{c}_{1}\right.$, $\mathbf{4 c}_{\mathbf{1}}$ ). These show two multiplets centred on the same chemical shift of the unlabelled species (ESI, Fig. S4 $\dagger$ ) and may be simulated by the use of two $\mathrm{AXNYZ}_{3}$ models $\left(\mathrm{A}, \mathrm{X}={ }^{31} \mathrm{P} ; \mathrm{N}={ }^{15} \mathrm{~N} ; \mathrm{Y}\right.$, $\mathrm{Z}={ }^{1} \mathrm{H}$ ) (see the Experimental section). The good fit between the experimental and calculated spectra strongly supports the presence of the two species having either cis-imine or transimine as a ligand. NOESY and COSY experiments are used to attribute the geometry of the two isomers.

Scheme 6

Scheme 7 [Os] $=\left[\mathrm{OsCl}\left(\eta^{6}-p \text {-cymene }\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]^{+}$.

The proton-coupled ${ }^{15} \mathrm{~N}$ NMR spectra of the two complexes $3 \mathbf{c}_{\mathbf{1}}$ and $\mathbf{4} \mathbf{c}_{\mathbf{1}}$ show two doublets of multiplets (ESI, Fig. $\mathrm{S} 5 \dagger$ ), as well as those of ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$, which fit the proposed formulation for the complexes.

## p-Cymene derivatives

The results obtained from the reaction of the cyclopentadienyl complexes of Os with the organic azide prompted us to extend our study to other half-sandwich derivatives such as $\left[\mathrm{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]$ and $\left[\mathrm{OsCl}_{2}\left(\eta^{6}-p\right.\right.$-cymene $)$ $\left.\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$. While the reaction of pentamethylcyclopentadienyl derivatives with the organic azide does not give any clear and reproducible results, $p$-cymene complexes quickly react with the organic azide, but do not afford $\kappa^{1}$-azide derivatives (Scheme 6).

Depending on the nature of the substituents, the reaction of both dichloro and chloro-triflate $p$-cymene derivatives $\left[\mathrm{OsCl}_{2}\left(\eta^{6}-p\right.\right.$-cymene $\left.)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$ and $\quad\left[\mathrm{OsCl}\left(\kappa^{1}-\mathrm{OTf}\right)\right.$ $\left(\eta^{6}-p\right.$-cymene $\left.)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$ with organic azides affords the $\kappa^{1}$-imine complex $\quad\left[\mathrm{OsCl}\left(\eta^{6}-p\right.\right.$-cymene $)\left\{\kappa^{1}\right.$ - $\mathrm{NH}=\mathrm{C}(\mathrm{H}) \mathrm{C}_{6} \mathrm{H}_{4}-4$ $\left.\left.\mathrm{CH}_{3}\right\}\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4}$ (6) and $\kappa^{1}$-amine derivative $\left[\mathrm{OsCl}\left(\eta^{6}-p\right.\right.$ cymene) $\left.\left(\kappa^{1}-\mathrm{NH}_{2} \mathrm{C}_{6} \mathrm{H}_{5}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4}$ (7). In any case, no evidence of the formation of $\kappa^{1}$-azide complexes was detected with the $p$-cymene derivatives. However, based on our previous results, we can hypothesise that organic azide $\mathrm{RN}_{3}$ substitutes the $\mathrm{Cl}^{-}$or $\mathrm{OTf}^{-}$ligand in the $p$-cymene precursors, affording the $\kappa^{1}$-azide derivative $\left[\operatorname{OsCl}\left(\eta^{6}-p\right.\right.$-cymene $\left.)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{R}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$ $\mathrm{BPh}_{4}[\mathrm{~A}]$ (Scheme 7). This intermediate is probably unstable and can give, in the case of $p$-tolylbenzylazide, the $\kappa^{1}$-imine derivative 6.

Instead, in the presence of ethanol, decomposition of the phenylazide intermediate [A] affords the aniline derivative 7, which was isolated in good yield and characterised. Its formation is not unexpected because it is well known ${ }^{20}$ that an azide can be reduced to an amine by an alcohol and the reaction is catalysed by transition metal complexes. As phenylazide cannot give an imine after the extrusion of $\mathrm{N}_{2}$ and the frag-
ment $\left[\operatorname{OsCl}\left(\eta^{6}-p \text {-cymene }\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]^{+}$does not bind $\mathrm{N}_{2}$, reduction by alcohol of the coordinate $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~N}_{3}$ is the easiest reaction of the intermediate [A] giving 7 .

Good analytical data were obtained for the $p$-cymene complexes 6 and 7, which were separated as yellow solids stable both in air and in solution of polar organic solvents, where they behave as 1:1 electrolytes. ${ }^{13}$ Infrared and NMR spectra support the proposed formulation. In particular, the ${ }^{1} \mathrm{H}$ NMR spectrum of the imine complex $\left[\operatorname{OsCl}\left(\eta^{6}-p\right.\right.$-cymene $)\left\{\kappa^{1}-\mathrm{NH}=\mathrm{C}\right.$ $\left.\left.(\mathrm{H}) \mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{CH}_{3}\right\}\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4}$ (6) shows a broad doublet at 10.99 ppm , attributed to the iminic NH proton. Besides the signals of the ancillary ligands $p$-cymene and $\mathrm{P}(\mathrm{OEt})_{3}$ and of anion $\mathrm{BPh}_{4}$, the proton spectra also show another doublet at 8.68 ppm , which, in a COSY experiment, is correlated with the broad doublet at 10.99 ppm and is attributed to the $=\mathrm{CH}$ proton of the imine ligand. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectrum is a sharp singlet at 67.51 ppm and fits the proposed formulation for the complex.

The IR spectrum of the amine complex [ $\operatorname{OsCl}\left(\eta^{6}-p\right.$-cymene $)$ $\left.\left(\kappa^{1}-\mathrm{NH}_{2} \mathrm{Ph}\right)\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4}$ (7) shows two medium-intensity bands at 3286 and $3226 \mathrm{~cm}^{-1}$, attributed to the $\nu_{\mathrm{NH}}$ of the aniline ligand. Its presence is confirmed using the ${ }^{1} \mathrm{H}$ NMR spectrum, which shows two broad signals at 5.52 and 5.81 ppm , attributed to the $\mathrm{NH}_{2}$ protons of the coordinate aniline. The presence of the two signals is due to the fact that the osmium atom is a chiral centre in the molecule. Signals of the supporting ligands are also present in the spectra, whereas the ${ }^{31} \mathrm{P}$ spectrum is a singlet at 68.29 ppm , in agreement with the proposed formulation for the complex.

## Conclusions

In this paper we report that the half-sandwich fragment $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right]^{+}$can stabilise organic azide complexes $\quad\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{R}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}$. Spectroscopic data suggest the $\kappa^{1}$-diazoamino coordination mode of the azide ligand. Also, imine derivatives $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\right.$
$\left.\left\{\kappa^{1}-\mathrm{NH}=\mathrm{C}(\mathrm{R} 2) \mathrm{Ar}\right\}\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}\left(\mathrm{R} 2=\mathrm{H}, \mathrm{CH}_{3}\right)$ were also obtained from benzylazide complexes. Instead, the dinuclear dinitrogen derivative $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}_{2}\left(\mu-\mathrm{N}_{2}\right)\right]$ $\left(\mathrm{BPh}_{4}\right)_{2}$ was prepared from phenylazide $\mathrm{PhN}_{3}$ compounds. Imine $\left[\operatorname{OsCl}\left(\eta^{6}-p\right.\right.$-cymene $\left.)\left\{\mathrm{\kappa}^{1}-\mathrm{NH}=\mathrm{C}(\mathrm{H}) \mathrm{R} 2\right\}\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}$ and amine complexes $\left[\mathrm{OsCl}\left(\eta^{6}-p\right.\right.$-cymene $\left.)\left(\kappa^{1}-\mathrm{NH}_{2} \mathrm{Ph}\right)\left\{\mathrm{P}(\mathrm{OR} 1)_{3}\right\}\right] \mathrm{BPh}_{4}$ stabilised by the $p$-cymene fragment were also prepared.

## Experimental

## Materials and physical measurements

All reactions were carried out in an inert atmosphere (argon) by means of standard Schlenk techniques or in an inert-atmosphere glove box. Once isolated, the complexes were found to be relatively stable in air, but were stored under nitrogen at $-25^{\circ} \mathrm{C}$. All solvents were dried over appropriate drying agents, degassed on a vacuum line, and distilled into vacuum-tight storage flasks. $\mathrm{OsO}_{4}$ was a Pressure Chemical Co. (USA) product, used as received. The phosphites $\mathrm{P}(\mathrm{OMe})_{3}$ and $\mathrm{P}(\mathrm{OEt})_{3}$ were Aldrich products, purified by distillation under nitrogen. Benzyl ${ }^{21}$ and phenyl ${ }^{22}$ azides were prepared following methods previously reported. The labelled benzylazides $4-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2}{ }^{15} \mathrm{~N}_{3}$ and $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}\left(\mathrm{CH}_{3}\right)^{15} \mathrm{~N}_{3}$ were prepared by following the same method, ${ }^{19}$ by reacting $\mathrm{Na}\left[{ }^{15} \mathrm{NNN}\right]$ ( $98 \%$ enriched, CIL) with either 4-methylbenzylbromide 4 - $\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{Br}$ or (1-bromoethyl)benzene $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{Br}$. Equimolar mixtures of $4-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2}{ }^{15} \mathrm{NNN}$ and $4-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{NN}^{15} \mathrm{~N}$ and of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}\left(\mathrm{CH}_{3}\right)^{15} \mathrm{NNN}$ and $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{NN}^{15} \mathrm{~N}$ were obtained. Other reagents were purchased from commercial sources in the highest available purity and used as received. Infrared spectra were recorded on a Perkin Elmer Spectrum-One FT-IR spectrophotometer. NMR spectra $\left({ }^{1} \mathrm{H},{ }^{31} \mathrm{P},{ }^{15} \mathrm{~N}\right)$ were obtained on an AVANCE 300 Bruker spectrometer at temperatures between -90 and $+30^{\circ} \mathrm{C}$, unless otherwise noted. ${ }^{1} \mathrm{H}$ spectra are referred to internal tetramethylsilane; ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ chemical shifts are reported with respect to $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$, whereas ${ }^{15} \mathrm{~N}$ shifts with respect to $\mathrm{CH}_{3}{ }^{15} \mathrm{NO}_{2}$; in both cases, downfield shifts are considered positive. COSY, HMQC and HMBC NMR experiments were performed with standard programs. The iNMR software package ${ }^{23}$ was used to process NMR data. The conductivity of $10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$ solutions of the complexes in $\mathrm{CH}_{3} \mathrm{NO}_{2}$ at $25^{\circ} \mathrm{C}$ was measured on a Radiometer CDM 83. Elemental analyses were determined in the Microanalytical Laboratory of the Dipartimento di Scienze Farmaceutiche, University of Padova (Italy).

## Synthesis of the complexes

The complexes $\left[\operatorname{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)_{2}\right]$ and $\left[\mathrm{OsCl}_{2}\left(\eta^{6}-p\right.\right.$-cymene $)$ $\left.\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$ were prepared following the methods previously reported. ${ }^{24,25}$
$\left[\operatorname{OsBr}\left(\boldsymbol{\eta}^{5}-\mathbf{C}_{5} \mathbf{H}_{5}\right)\left(\mathbf{P P h}_{3}\right)\left\{\mathbf{P}(\mathbf{O R 1})_{3}\right\}\right][\mathbf{R 1}=\mathbf{M e}, \mathbf{E t}]$. An excess of the appropriate phosphite $\mathrm{P}(\mathrm{OR} 1)_{3}(8 \mathrm{mmol})$ was added to a solution of $\left[\operatorname{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)_{2}\right](1.72 \mathrm{~g}, 2 \mathrm{mmol})$ in 50 mL of toluene and the reaction mixture was refluxed for 1 h . The solvent was removed under reduced pressure to leave an oil,
which was triturated at $0^{\circ} \mathrm{C}$ with ethanol ( 2 mL ). A yellow solid slowly separated out, which was filtered and dried under vacuum; yield $\geq 80 \%$.
$R 1=M e .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, 20^{\circ} \mathrm{C}\right) \delta: 7.52,7.32(\mathrm{~m}, 15 \mathrm{H}, \mathrm{Ph})$, 4.65 (s, 5H, Cp), $3.41\left(\mathrm{~d}, 9 \mathrm{H}, \mathrm{CH}_{3}\right) ;{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right.$, $\left.20^{\circ} \mathrm{C}\right) \delta$ : AX spin syst, $\delta_{\mathrm{A}} 100.45, \delta_{\mathrm{X}} 6.55, J_{\mathrm{AX}}=41.4$; anal. calcd for $\mathrm{C}_{26} \mathrm{H}_{29} \mathrm{BrO}_{3} \mathrm{OsP}_{2}$ (721.59): C, $43.28 ; \mathrm{H}, 4.05 ; \mathrm{Br}, 11.07$; found: C, 43.41; H, 3.96; Br, 11.28\%.

$\left[\left\{\mathbf{O s}\left(\boldsymbol{\eta}^{5}-\mathrm{C}_{5} \mathbf{H}_{5}\right)\left(\mathbf{P P h}_{3}\right)\left[\mathbf{P}(\mathbf{O M e})_{3}\right]\right\}_{2}\left(\boldsymbol{\mu}-\mathbf{N}_{2}\right)\right]\left(\mathrm{BPh}_{4}\right)_{2}$ (5). Method 1: A solution of the phenylazide complex $\left[\mathrm{Os}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\kappa^{1}-\mathrm{N}_{3} \mathrm{Ph}\right)\right.$ $\left.\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}\right] \mathrm{BPh}_{4}(\mathbf{1 d})(100 \mathrm{mg}, 0.09 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(5 \mathrm{~mL})$ was stirred at room temperature for 1 h . The solvent was removed under reduced pressure to give an oil, which was triturated with ethanol ( 1 mL ). A blue solid slowly separated out, which was filtered and twice crystallised from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and ethanol; yield $\geq 55 \%$.

Method 2: In a 25 mL three-necked round-bottomed flask were placed $0.14 \mathrm{mmol}(100 \mathrm{mg})$ of the complex $\left[\operatorname{OsBr}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}\right]$, a slight excess of AgOTf $(0.15 \mathrm{mmol}, 39 \mathrm{mg}$ ) and 5 mL of toluene. The reaction mixture
was stirred in the dark for 75 min and then filtered to remove the AgBr formed. An excess of phenylazide $(0.18 \mathrm{mmol}$, $21.5 \mu \mathrm{~L}$ ) in 5 mL of dichloromethane was added to the resulting solution, and cooled to $-196{ }^{\circ} \mathrm{C}$. The reaction mixture was left to reach room temperature and then stirred for 1 h . The solvent was removed under reduced pressure to give an oil, which was triturated with ethanol ( 1 mL ) containing an excess of $\mathrm{NaBPh}_{4}(0.28 \mathrm{mmol}, 96 \mathrm{mg})$. A blue solid slowly separated out, which was filtered and twice crystallised from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and ethanol; yield $\geq 45 \%$. ${ }^{1} \mathrm{H}$ NMR $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 20^{\circ} \mathrm{C}\right] \delta: 7.61-6.77$ (m, $70 \mathrm{H}, \mathrm{Ph}$ ), $5.03(\mathrm{~s}, 10 \mathrm{H}, \mathrm{Cp}), 3.61\left(\mathrm{~d}, 18 \mathrm{H}, \mathrm{CH}_{3}\right) ;{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left[\left(\mathrm{CD}_{3}\right)_{2} \mathrm{CO}, 20^{\circ} \mathrm{C}\right] \delta: \mathrm{AX}$ spin syst, $\delta_{\mathrm{A}} 90.21, \delta_{\mathrm{X}} 6.24, J_{\mathrm{AX}}=$ 38.5; anal. calcd for $\mathrm{C}_{100} \mathrm{H}_{98} \mathrm{~B}_{2} \mathrm{~N}_{2} \mathrm{O}_{6} \mathrm{Os}_{2} \mathrm{P}_{4}$ (1949.83): C, 61.60; $\mathrm{H}, 5.07$; N, 1.44 ; found: C, 61.41 ; $\mathrm{H}, 5.16 ; \mathrm{N}, 1.33 \% ; \Lambda_{\mathrm{M}}=$ $58.8 \Omega^{-1} \mathrm{~mol}^{-1} \mathrm{~cm}^{2}$.
$\left[\operatorname{OsCl}\left(\eta^{6}-p\right.\right.$-cymene $\left.)\left\{\boldsymbol{\kappa}^{\mathbf{1}}-\mathrm{NH}=\mathrm{C}(\mathbf{H}) \mathrm{C}_{6} \mathbf{H}_{4}-\mathbf{- 4}-\mathrm{CH}_{3}\right\}\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right] \mathrm{BPh}_{4}$ (6). Method 1: In a 25 mL three-necked round-bottomed flask were placed $80 \mathrm{mg}(0.14 \mathrm{mmol})$ of $\left[\mathrm{OsCl}_{2}\left(\eta^{6}-p\right.\right.$-cymene $)$ $\left.\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$, a slight excess of AgOTf $(0.15 \mathrm{mmol}, 39 \mathrm{mg})$ and 5 mL of dichloromethane. The reaction mixture was stirred in the dark for 24 h , filtered to remove the AgCl formed, and then an excess of $4-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{~N}_{3}(0.42 \mathrm{mmol}, 62 \mu \mathrm{~L})$ added. The reaction mixture was stirred for 6 h and then the solvent was removed under reduced pressure. The oil obtained was triturated with ethanol ( 1 mL ) containing an excess of $\mathrm{NaBPh}_{4}$ ( $0.28 \mathrm{mmol}, 96 \mathrm{mg}$ ). A yellow solid slowly separated out from the resulting solution, which was filtered and crystallised from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and ethanol; yield $\geq 75 \%$.

Method 2: In a 25 mL three-necked round-bottomed flask were placed 80 mg ( 0.14 mmol ) of $\left[\mathrm{OsCl}_{2}\left(\eta^{6}-p\right.\right.$-cymene) $\left.\left\{\mathrm{P}(\mathrm{OEt})_{3}\right\}\right]$, an excess of $\mathrm{NaBPh}_{4}(0.28 \mathrm{mmol}, 96 \mathrm{mg}), 5 \mathrm{~mL}$ of dichloromethane, and 5 mL of ethanol, and an excess of $4-\mathrm{CH}_{3} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{~N}_{3}(0.42 \mathrm{mmol}, 62 \mu \mathrm{~L})$ was added. The reaction mixture was stirred for 24 h and then the solvent was removed under reduced pressure. The oil obtained was triturated with ethanol ( 1 mL ) until a yellow solid separated out from the resulting solution, which was filtered and crystallised from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and ethanol; yield $\geq 70 \%$.

## Crystal structure determinations

Crystallographic data for 5 were collected at CACTI (University of Vigo, Spain) at 100 K (CryoStream 800) using a Bruker D8 Venture Photon 100 CMOS detector and Mo-K $\alpha$ radiation ( $\lambda=$ $0.71073 \AA$ ) generated by a Incoatec high brilliance $\mathrm{I} \mu \mathrm{S}$ microsource. The software APEX3 ${ }^{26}$ was used for collecting frames of data, indexing reflections, and the determination of lattice parameters, SAINT ${ }^{26}$ for the integration of the intensities of reflections, and SADABS ${ }^{26}$ for scaling and empirical absorption correction. The crystallographic treatment was performed with the Oscail program ${ }^{27}$ solved using the SHELXT program. ${ }^{28}$ The structure was subsequently refined by a fullmatrix least-squares based on $F^{2}$, SHELXL program. ${ }^{29}$ Nonhydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atoms were included in idealized positions and refined with isotropic displacement parameters. Other details of crystal data and structural refinement are given in Table 2. CCDC $1846339 \dagger$ contains the supplementary crystallographic data for this paper.

Table 2 Crystal data and structure refinement

| Compound | 5 |
| :---: | :---: |
| Empirical formula | $\mathrm{C}_{102} \mathrm{H}_{102} \mathrm{~B}_{2} \mathrm{Cl}_{4} \mathrm{~N}_{2} \mathrm{O}_{6} \mathrm{Os}_{2} \mathrm{P}_{4}$ |
| Moiety formula | $\mathrm{C}_{52} \mathrm{H}_{58} \mathrm{~N}_{2} \mathrm{O}_{6} \mathrm{Os}_{2} \mathrm{P}_{4}, 2\left(\mathrm{C}_{24} \mathrm{H}_{20} \mathrm{~B}\right), 2\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ |
| Formula weight | 2119.55 |
| Temperature | 100(2) K |
| Wavelength | 0.71073 A |
| Crystal system | Triclinic |
| Space group | $P \overline{1}$ |
| Unit cell dimensions | $a=12.7763(19) \AA$ |
|  | $b=13.497(2) \AA$ |
|  | $c=14.717(2) \AA$ |
|  | $\alpha=63.354(4)^{\circ}$ |
|  | $\beta=86.818(5)^{\circ}$ |
|  | $\gamma=83.617(5)^{\circ}$ |
| Volume | 2254.3(6) $\AA^{3}$ |
| Z | 1 |
| Density (calculated) | $1.561 \mathrm{Mg} \mathrm{m}^{-3}$ |
| Absorption coefficient | $3.062 \mathrm{~mm}^{-1}$ |
| $F(000)$ | 1066 |
| Crystal size | $0.085 \times 0.072 \times 0.041 \mathrm{~mm}$ |
| $\Theta$ range for data collection | 2.222 to $28.356^{\circ}$ |
| Index ranges | $-17 \leq h \leq 17$ |
|  | $-18 \leq k \leq 18$ |
|  | $-19 \leq l \leq 19$ |
| Reflections collected | 85416 |
| Independent reflections | 11224 [ $\left.R_{\text {int }}=0.0344\right]$ |
| Reflections observed (>2 $)$ | 10461 |
| Data completeness | 0.997 |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.7457 and 0.6693 |
| Refinement method | Full-matrix least-squares on $F^{2}$ |
| Data/restraints/parameters | 11 224/0/553 |
| Goodness-of-fit on $F^{2}$ | 1.094 |
| Final $R$ indices $[I>2 \sigma(I)]$ | $R_{1}=0.0326$ |
|  | $\mathrm{w} R_{2}=0.0849$ |
| $R$ indices (all data) | $R_{1}=0.0364$ |
|  | $\mathrm{w} R_{2}=0.0867$ |
| Largest diff. peak and hole | 3.059 and -2.753 e $\AA^{-3}$ |

## Conflicts of interest

There are no conflicts of interest to declare.

## Acknowledgements

The financial support of MIUR (Italy) - PRIN 2016 is gratefully acknowledged. We thank Daniela Baldan, from the Università Ca’ Foscari Venezia (Italy), for technical assistance.
